INTRODUCTION

Biliopancreatic Diversion with Duodenal Switch, or BPD-DS, is a surgical procedure used in the treatment of Obesity. To learn more about this surgery, let us first learn about obesity and the normal digestive process.
What is Obesity?

Obesity is a serious, chronic disease that is a growing worldwide concern affecting the health of millions of people. Obesity is defined as an excessively high amount of body fat in relation to lean body mass resulting from caloric intake that exceeds energy usage.

Obesity is the second leading cause of preventable death following smoking.

The Gastrointestinal System:

The gastrointestinal system is essentially a long tube running through the body with specialized sections that are capable of digesting material put in the mouth and extracting any useful components from it, then expelling the waste products from the anus.

- Esophagus
- Stomach
- Small Intestine
- Large Intestine

(Fig. 1)

Food after ingestion undergoes three types of processes in the body: Digestion, Absorption, Excretion.

The entire GI system is under hormonal control with the presence of food in the mouth triggering a cascade of hormonal actions. When food reaches the stomach, different hormones activate acid secretion, increased gut motility, enzyme release etc.

Nutrients from the GI tract are not processed on-site but instead will be absorbed and taken to the liver through the blood circulation to be broken down further, stored, or distributed.
Esophagus

Once food is chewed and mixed with saliva in the mouth, it is swallowed and passes down the esophagus. The esophagus has a stratified squamous epithelial lining (SE) which protects the esophagus from trauma.

The submucosa lining (SM) secretes mucus from mucous glands (MG) which aid the passage of food down the esophagus. The esophageal wall muscle layer helps to push the food into the stomach by waves of motion called peristalsis.

(Refer fig. 2)

Stomach

The stomach is a 'j'-shaped organ with two openings- the esophageal and the duodenal- and four regions- the cardia, fundus, body and pylorus. Each region performs different functions including mixing of the food with digestive enzymes and strong acid. The layer of mucus produced prevents the stomach from digesting itself.

The stomach’s major functions are:

- Temporary food storage
- Control the rate at which food enters the small intestine
- Acid secretion and antibacterial action
- Fluidization of stomach contents
- Preliminary digestion with pepsin, lipases etc.

(Refer fig. 3)
Small Intestine

The small intestine is the site where most of the chemical and mechanical digestion is carried out, and where virtually all of the absorption of useful materials occurs. The whole of the small intestine is lined with an absorptive mucosal layer, with certain modifications for each section.

The intestine also has a smooth muscle wall with two layers of muscle; rhythmical contractions force products of digestion through the intestine (peristalsis).

There are three main sections to the small intestine:

- The duodenum forms a 'C' shape around the head of the pancreas. Its main function is to neutralize the acidic gastric contents (called 'chyme') and to initiate further digestion; Brunner’s glands in the submucosa secrete alkaline mucus which neutralizes the acidic chyme of the stomach and protects the surface of the duodenum.

- The jejunum and the ileum are the greatly coiled parts of the small intestine, and together are about 4-6 meters long or 13-20 feet; the junction between the two sections is not well-defined. The mucosa of these sections is highly folded (the folds are called plica), increasing the surface area available for absorption dramatically.

(Refer fig. 3)

Large Intestine

The large intestine is the last part of the digestive tube and the location of the terminal phases of digestion.

It is the part of the digestive tube between the terminal small intestine and anus. Within the large intestine, three major segments are recognized:

(Continued in next page)
The cecum is a blind-ended pouch that in humans carries a worm-like extension called the vermiform appendix.

The colon constitutes the majority of the length of the large intestine and is sub-classified into ascending, transverse, and descending segments.

The rectum is the short, terminal segment of the digestive tube, continuous with the anal canal.

Functions of the Large Intestine

- **Recovery of water and electrolytes from digested food:** A considerable amount of water and electrolytes like sodium and chloride remain and must be recovered by absorption in the large intestine. This is what goes wrong when you have diarrhea and constipation.

- **Formation and storage of feces:** As digested food passes through the large intestine, it is dehydrated, mixed with bacteria and mucus, and formed into feces.

- **Microbial fermentation:** Fermentation is the enzymatic decomposition and utilization of foodstuffs, particularly carbohydrates, by microbes. The large intestine does not produce its own digestive enzymes, but contains huge numbers of bacteria which have the enzymes to digest and utilize many substrates.
Body Mass Index BMI

Body Mass Index (BMI) is the measure of body fat based on height and weight that applies to both adult men and women. BMI does not differentiate between body fat and muscle mass. Therefore, body builders and people who have a lot of muscle bulk will have a high BMI but are not overweight or obese.

Overweight is defined as a Body Mass Index (BMI) of 25 to 29.9. Overweight refers to increased body weight in relation to height. Obesity is defined as a Body Mass Index (BMI) of 30 or higher and extreme obesity is a BMI of 40 or more. Extreme obesity is often referred to as Morbid Obesity due to the associated health risks.

Causes of Obesity

Obesity could be a combination of the following:

- The genes you inherited from your parents
- How well your body turns food into energy
- Your eating and exercising habits
- Your surroundings
- Psychological factors

Complications of Obesity

If you are obese, severely obese, or morbidly obese, you may have:
Major health risks

- **Shorter Life Expectancy**: Compared to people of normal weight, obese people have a 50% to 100% increased risk of dying prematurely

Obese people have more risk for:

- Diabetes (type 2)
- Joint problems (e.g., Arthritis)
- High blood pressure
- Heart disease
- Gallbladder problems
- Certain types of cancer (breast, uterine, colon)
- Breathing difficulties (e.g., sleep apnea, asthma)
- Problems with fertility and pregnancy
- Incontinence
- Digestive disorders (e.g., gastroesophageal reflux disease, or GERD)

Risks to psychological and social well-being

- Negative self-image
- Social isolation
- Discrimination

Difficulties with day-to-day living

- Normal tasks become harder when you are obese, as movement is more difficult
- You tend to tire more quickly and you find yourself short of breath
- Public transportation seats and car seats may be too small for you
- You may find it difficult to maintain personal hygiene
Surgical Procedure
Gastric Bypass: Biliopancreatic Diversion with Duodenal Switch Surgery

BPD-DS surgery, a modification of BPD surgery, combines a sleeve gastrectomy (removal of part of the stomach) with a long intestinal bypass.

In the sleeve gastrectomy part of the surgery, the outer margin of the stomach is removed, leaving a banana shaped stomach, ¼ of its original capacity, that remains connected to the duodenum. This creates the restrictive portion of the surgery.

(Refer fig. 7 to 11)
Biliopancreatic Diversion Duodenal Switch Surgery

In the sleeve gastrectomy part of the surgery, the outer margin of the stomach is removed, leaving a banana shaped stomach, ¼ of its original capacity, that remains connected to the duodenum. This creates the restrictive portion of the surgery.

The surgeon accomplishes this by dividing the first part of the duodenum between the stomach and bile duct and closing off the divided end.

Biliopancreatic Diversion Duodenal Switch Surgery The surgeon then divides the small intestine about half way down, connecting the lower portion to the open end of the duodenum. This segment is referred to as the digestive, or roux, limb.

(Refer fig. 12 to 15)
The remaining end of the small intestine is reconnected 75-100 cm from the large intestine creating the “common channel” allowing for bile and pancreatic juices to flow and mix with the food at the distal end of the small intestine, instead of in the duodenum, thereby limiting absorption of nutrients and calories.
Advantages of Gastric Bypass: Biliopancreatic Diversion with Duodenal Switch Surgery

Advantages of Gastric Bypass BPD-DS Surgery includes:

- Quick and dramatic weight loss
- Excellent long term weight loss results
- Unrestricted diet
- Able to eat larger portions of food than “pouch” surgeries
- Pyloric valve is left intact essentially eliminating “Dumping Syndrome”
- Normal stomach function is maintained but in a smaller capacity
- Reduced incidence of stomach ulcers due to removal of most of the acid secreting cells in stomach
- Continued weight loss for 18-24 months post surgery
- Many patients maintain a weight loss of 75-80% of excess weight 10 years post-op
- Improved health problems associated with severe obesity (ie. Diabetes, high blood pressure, sleep apnea, etc.)
- Improved mobility and quality of life

Disadvantages of Gastric Bypass: Biliopancreatic Diversion with Duodenal Switch Surgery

Disadvantages to BPD with duodenal switch surgery include:

- Major surgery with serious risks
- Most complicated of currently available obesity surgeries
- Limited number of surgeons performing this procedure via laparoscopy
- Usually performed as open operation instead of Laparoscopically, with associated risks
- Risk of death 1:100 surgeries
- Longer recovery time, usually 6-8 weeks
- Potential for protein malnutrition
- Malnourishment and anemia may occur requiring life long vitamin and mineral supplementation
- Malabsorptions require life long supplementation of fat soluble vitamins (A, D, E, and K), B12, calcium, and iron.

Unit 3:  Duodenal Switch Surgery

- Life long follow up with physician equired
- Risk of iron deficiency anemia and osteoporosis if supplements not taken
- Increased risk of gallstones due to rapid weight loss
- Requires gallbladder removal during surgery due to high risk of gallstones
- Not possible to fully reverse due to partial removal of stomach
- Dumping syndrome: nausea, reflux, diarrhea can occur after ingesting high sugar foods
- Increased stool frequency to 2-4/day
- Hospital stay of 3-5 days usually
- Foul flatulence and diarrhea if fatty foods eaten
- Risk of hair loss

Risks & Complications

As with any surgery there are potential risks involved. The decision to proceed with the surgery is made because the advantages of surgery outweigh the potential disadvantages. It is important that you are informed of these risks before the surgery takes place.

Most patients do not have complications after Gastric Bypass BPD-DS surgery; however complications can occur and depend on the patient’s health status. Complications can be medical (general) or specific to Gastric Bypass BPD-DS.

Medical complications include those of the anesthesia and your general well being. Almost any medical condition can occur so this list is not complete.

Complications include:

- Allergic reaction to medications
- Blood loss requiring transfusion with its low risk of disease transmission
- Heart attack, strokes, kidney failure, pneumonia, bladder infections
- Complications from anesthesia
- Serious medical problems can lead to ongoing health concerns, prolonged hospitalization, or rarely death. (Less than 1% cases)

(Continued in next page)
Specific complications for Gastric Bypass BPD-DS include:

- DVT (blood clot in the deep leg veins)
- Damage to adjacent organs especially spleen, pancreas and bile duct
- Abdominal hernia
- Leakage of digestive contents can lead to serious infection (Peritonitis)
- Leakage of digestive contents from the staple line can lead to serious infection
- Stricture (narrowing) of the opening between the stomach and small intestine
- Dumping Syndrome: Vomiting, reflux, and diarrhea caused by stomach contents moving too rapidly through the small intestine
- Abdominal hernias
- Gallstones
- Dehydration
- Bleeding ulcers of the stomach
- Intolerance to some foods
